

With the first wireframe what I am going for is basically the google feel of things like they do for personal emails but with this it is directed towards a work email. It will auto filter to fit 3 categories, work, personal, and misc for all the other crap. At the bottom of the page it will show a possible junk that is filtered out of the regular inbox. This way looking for emails is much faster and if you see a work email in possible junk you can move it back to regular. This will make things much easier to organize and it will auto delete the junk after 30 days if you chose to. The goal is simplicity and straight forwards/ ease of access.

With this second design the main goal was to make everything manual so automation does not make mistakes. You have your regular inbox but then when you enter the email it gives the subject and email address of the sender. Next to those two items is a button that says "Mark as work" to make it into the work folder. BY doing this is makes looking and searching through your work emails will be simple and fast. With this if it is a recurring sender it will show below all of their past emails, this way you will have all of your emails from a sender in one spot. Within there you can search for phrases and words to make it easy to find information. Very simple and manual is the goal I was reaching for in this design.
